1. AAS in AI Software Engineering
2. PY101
3. Writing your first program

Today

Welcome to your next lesson: Writing your first program.

I'm getting your personalized lesson ready—using what you've learned so far, what's coming up next, and the best way to help everything stick.

Step by step, you're moving forward.

Ron, this is where you write your very first real Python program ?

Think of the Maestro Code Editor as your workbench or artist's canvas for code: it's where you type, run, and see what your Python code does.

To open it in this lesson, look for the `</>` button on your screen and click it. That should open the editor with a place to type and an area where the output will show.

Can you tell me once you've found and opened the editor with the `</>` button? Then we'll put your first line of Python on that canvas.

> I found the editor

Nice work getting there, Ron ?

Now we'll write your very first Python program.

Step 1: In the editor's typing area, delete anything that's there.

Step 2: Type exactly this line in the editor (don't type it in chat):

Python
```python
print('Hello World')
```

When you've typed it into the editor, don't run it yet—just tell me "done" and we'll talk about what this line is doing before you hit Run.

Perfect ?

The line you typed uses `print()`. In simple terms:

> *`print()` tells Python: "show this message on the screen."*

The text you want to show goes inside the parentheses, wrapped in quotes:

`'Hello World'` is just a piece of text.

Next step:

1. In the editor, click the Run button (not Submit yet).
2. Look at the output/console area.

You should see:

Text
```
Hello World
```

(without the quotes)

Run it now, then tell me what you see in the output area.

Python
```
print('Hello World')
```

Ron, you just ran your first Python program ? That's a real milestone.

You told Python: "show the message `Hello World` on the screen," and the console did exactly that.

Quick reflection question (no right/wrong vibe, just thinking):

Why do you think so many programmers start with a tiny program like `Hello World` instead of something bigger—what's your guess?

> I also just learned something about Python. It is case-sensitive. I had `print` with a capital P and got an error. The `print` was undefined. I had to come back and review and realized it's lowercase only

Exactly right — great catch ?

Python is case-sensitive, so:

- **`print`**`('Hello World')` → works ✓
- **`Print`**`('Hello World')` or **`PRINT`**`('Hello World')` → Python thinks this is something completely different and says it's not defined ✕

You just did something very "real programmer": you hit an error, read it, thought about it, and fixed it. That's the core loop of coding ?

Want to do one tiny variation to lock this in?

In the editor, change your line to:

Python
```
print('Hello Ron')
```

Then:

1. Click Run
2. If it looks good, click Submit code

Don't paste the code here—just run and submit it, and I'll check it.

Python
```
print('Hello Ron')
```

What do you think? ? Choose your answer in the question box above.

When you want to try your code locally first in the Maestro Code Editor, which button should you click first?

A.

Run

B.

Run & Submit

You nailed it, Ron ?

Maestro can make mistakes. Check important info.

Run is exactly the right choice:

- Run ? lets you test your code yourself, see the output, and fix anything before anyone else sees it.
- Run & Submit ? is for when you’re happy with the result and want to submit it for review.

You’ve now:

- Opened the Maestro Code Editor
- Written and run `print('Hello World')`
- Tweaked it to `print('Hello Ron')`
- Used Run vs Run & Submit correctly

That’s everything for this lesson’s goals ✅

Before we wrap this lesson:

Do you feel ready to move on to the next lesson, or would you like to do one more quick practice with `print()` first?

I'm ready to move on

Nice work, Ron — that was a clean first win ?

In this lesson you:

- Opened the Maestro Code Editor using the `</>` button
- Wrote and ran `print('Hello World')` and then customized it to `print('Hello Ron')`
- Saw how Run lets you test code, and Run & Submit sends it in when you’re happy
- Discovered on your own that Python is case-sensitive (`print` ≠ `Print`) ?

You’ve got the basics of writing and running a Python program down.

When you’re ready, go ahead and hit Next Lesson in the Learn tab, and we’ll build on this together.
