Welcome to your next lesson: Working with text.

I'm preparing your personalized lesson based on what you've learned, what's ahead, and how to help you build even more skills.

Step by step, you're moving forward.

- Imagine we're writing a little Python program that talks about your favorite band ?

Example:

```python
band = "Metallica"
message = "is playing tonight!"
print(band + message)
```

Python is working with text here, not numbers. In programming, we call this kind of thing a data type.

> *Data type = a category of data (like text, number, True/False) that decides what you can do with it.*

So `"Metallica"` is text, and text belongs to the string data type.

Quick check before we go on:

Does this idea of "data type = category of data that decides what you can do with it" make sense so far, or should I rephrase it a bit?

> makes tota sense used to integers floats boolean strings with c

Nice, that background will help a lot ?

In Python, that text data type is called a string. You make a string by putting text inside quotes:

```python
"Hello"
'Python'
"Metallica"
```

Single quotes `' '` or double quotes `" "` both work the same for strings in Python.

Quick step:

Can you tell me (just in words): if you write `"Hello"` in Python, is that a string or something else?

> its in quotes so it should be a string

Exactly right — in quotes ⇒ it's a string ?

Now let's use that with variables and the `+` operator.

In Python, `+` between strings means: glue the text together (this is called concatenation).

Example:

Python

```
first = "Metallica"
second = " rocks"
print(first + second)
```

This takes the text in **first** and the text in **second** and sticks them together into one longer string.

Quick mental check (no code editor yet):

Without running it, what do you think `print(first + second)` will show on the screen in that example?

Metallica rocks

Exactly: Metallica rocks ?

Now let's make two strings and glue them ourselves.

Remember:

- Put text in quotes → string
- Use `+` between strings → join them with no extra spaces added automatically

For example:

Python

```
artist = "Metallica"
song = "Nothing Else Matters"
print(artist + " - " + song)
```

Step by step, Python builds one big string from pieces:

- "Metallica"
- " - "
- "Nothing Else Matters"

Your turn (in the code editor, not in chat):

1. Make a variable for an artist name (string in quotes).
2. Make a variable for a song title (string in quotes).
3. Use **print**(...) with `+` to show something like: Artist - Song
4. Run it, then Submit code.

After you submit, I'll help you predict and read the output together ?

Python

```
artist = "Ozzy Osbourne"
song = "Over The Mountain"
print(artist + " - " + song)
```

Love it ?

Your code:

Python

```
artist = "Ozzy Osbourne"
```

```
song = "Over The Mountain"
print(artist + " - " + song)
```

Output:

```
Ozzy Osbourne - Over The Mountain
```

This shows you've got:

- string variables ✅
- concatenation with `+` ✅
- predicting printed output ✅

One more tiny thing to lock in the idea of `+` as the "text glue":

Which operator in Python joins two pieces of text (strings) together?

I'll put this as a quick multiple-choice question next — ready to answer that?

yes

What do you think? ?

Which operator in Python glues two strings together (concatenates them)?

A.

*

B.

+

C.

-

Correct — + is the string glue in Python ?

- When both sides are strings, `+` concatenates them:

```
"Ozzy" + " Osbourne"  # → "Ozzy Osbourne"
```

- Python does not add spaces for you, so you did the right thing by including `" - "` in quotes.

You've hit all the goals for this lesson:

- You know what a data type is.
- You can create string variables with quotes.
- You can combine strings with `+`.
- You can predict print output from string code.

Do you feel ready to wrap up this lesson and move to the next one, or would you like one more quick practice with strings first?

im fine with moving ahead

Nice work today, Ron ?

Quick recap of what you just mastered:

- A data type is a category of data (like text) that decides what you can do with it.
- Text in Python is a string, and you create it by putting characters in single or double quotes.

- The + operator between strings glues text together (concatenation).
- You can predict what print(...) will show by mentally joining the string pieces.

Your Ozzy example was spot on:

```
artist = "Ozzy Osbourne"
song = "Over The Mountain"
print(artist + " - " + song)
```

You're all set to move ahead ?

When you're ready, go to the next lesson in the Learn tab, and I'll keep building on this with you.

How would you rate this lesson?
