Review: thinking in objects

Today

Hey Ron! Nice work reaching the end of this week.

How are you feeling about everything you've learned so far?

I feel confident

That's great to hear! Confidence is key.

Just a quick reminder before you start:

This review is worth 10% of your final grade.
You can retry as many times as needed until you pass.
It's graded as pass or fail, so you'll get full points if you pass.
If you submit all reviews in this course on time, you'll earn a bonus toward your final grade.

If you want help, review previous lessons or try the practice section before submitting.

Are you ready to begin the review now?

yes

Awesome!

Once you submit your answers, it'll take just a few seconds to get your results.

Good luck—you've got this!

Go ahead and click the "Review" button below to get started.

Thank you for completing the review. Below is feedback on your submission.

 Performance summary

Result: Passed ✅

You successfully completed all ten questions, earning credit across both the multiple-choice and open-text sections. Your responses demonstrated solid understanding of classes, instances, attributes, methods, modules, and object-oriented organization. To strengthen your work further, focus on making explanations more precise, clearly contrasting related concepts, and connecting technical ideas to practical effects such as maintainability and readability.

🔍 Detailed Assessment Feedback

Question 6 – You show the main idea that the second framing is about defining objects by what they know and can do, and you also mention modular, reusable code and class blueprints. That demonstrates a solid shift toward object-based thinking. To score higher, your explanation needed a clearer contrast with the step-by-step/sequential view and a stronger explanation of why keeping data together with the behavior that uses it makes programs easier to extend and maintain.

Question 7 – This is a strong answer. You clearly identify that car1 and car2 are separate instances and explain that they hold separate data, so changing one does not change the other. You also connect this well to the idea of the class as a shared blueprint. The only reason this is not full credit is that the explanation of how the class relates to instance attributes could be a little more direct and polished.

Question 8 – Good response. You correctly explain that a module provides reusable code such as functions, classes, and variables, and you identify a practical downside of from ... import *: name conflicts as the file grows. That matches the core grading criteria well. To make it even stronger, you could have also emphasized readability or how it becomes harder to tell where a name came from.

Question 9 – You show the main idea that r is the same object and that repeated method calls can produce different results. That demonstrates basic understanding. However, your answer does not clearly separate the three things the question asked for: the object r, the method being called, and the returned data. Also, saying it returns a "completely random number" is looser than needed here. A more precise explanation would have made this stronger.

Question 10 - This is a strong answer. You correctly explain that type(bag) shows bag is an instance of Backpack, and you distinguish a class as a blueprint from the created object. You also give a practical reason this matters when reading code: it helps you understand what methods and behaviors the object may have. The answer meets the criteria well; it would only be stronger with slightly clearer wording around class definition versus object creation.

You have successfully completed the review, and your effort shows a strong foundation in object-oriented programming concepts.
