```
print(total)            # 2275
print(very_large_found) # True
```

You never break, so total includes all numbers.
very_large_found becomes True when it hits 1200 and stays True.

You've now shown you can:

use a boolean flag in a loop
maintain a running accumulator
decide intentionally whether to use break or not
Let's do one last quick multiple-choice question to lock in the "flag + accumulator + break" trio, then we can wrap this lesson up 🎓

What do you think? Ready for that final MCQ?

Yes, I'm ready!

What do you think this one does? Walk through it step by step in your head, then pick an answer below 👇

Look at this Python code:

```
nums = [3, 6, -4, 10]

flag = False
total = 0

for n in nums:
    if n < 0:
        flag = True
        break
    total += n

print(total)
print(flag)
```

What will this program print?

A.

9 then True

B.

15 then True

C.

9 then False

D.

0 then True

You crushed that final question, Ron 🎯

Quick replay of the code:

```
nums = [3, 6, -4, 10]

flag = False
total = 0

for n in nums:
    if n < 0:
        flag = True
        break
```

```
523         total += n
524 
525     print(total)
526     print(flag)
```
